

Diodes

Ideal Diode

$-V_F (V_{\text{forward}}) = 0$ (in ideal)

Characteristic Curve (Ideal case):

Ideal Diode (Modes of Operation):

Forward Biased

←————→
- Ideal scenario,
time it takes to switch
between these states
 $\Delta t = 0$. (Only in Ideal)

Reverse Biased

Practical Diode

- Forward Voltage Voltage drop across the diode when its conducting and current is flowing in the positive direction

- Reverse - Break - Down Voltage. The voltage when the diode is reverse biased where it will begin conducting in the reverse direction (ie: 1000V) - Damages diode

- On - Resistance

- Turn on/off times

Diode Turn off Time:

- Fast Recovery Diodes, Reverse Recovery time is shorter

Losses

Conduction $\rightarrow P_{cond} = V_F \cdot I_F \cdot D$ (Dominant at Low Frequencies)
 $P_{cond} = I_O^2 \cdot R_{DS(on)}$

Switching \rightarrow (Increases with turn ON/turn OFF time)
(Increases with Switching Frequency)
 $P_{sw} = (\text{Losses per switch (Q)}) (\text{Time of one period})$
ie: How many switches per second
